(54) Title: METHOD FOR IMMUNO-DETECTION OF EPITOPEs

(57) Abstract: Methods, systems and kits are provided for detecting molecules expressing a selected epitope in a sample through use of an epitope detector containing a single chain Fv for the selected epitope or a constrained epitope specific CDR attached to an oligonucleotide.

METHOD FOR IMMUNO-DETECTION OF EPITOPES

Background of the Invention

One of the central problems in cell biology and medicine relates to the inability to monitor protein, 5 lipids, sugars and metabolite levels and their modifications in the single living cell. A variety of technologies have been employed to improve the sensitivity of detecting these molecules.

For example, to increase the sensitivity of 10 immunoassays able to detect proteins at very low amounts, the polymerase chain reaction (PCR) technology has been combined with conventional immuno-detection methods ((U.S. Patent 5,665,539)). This technology, termed immuno-PCR, provides an extremely sensitive method to detect proteins. 15 In immuno-PCR, a linker molecule with bi-specific binding affinity for DNA and antibody is used to attach a marker DNA molecule specifically to an antigen-antibody complex, thus resulting in the formation of a specific antigen-antibody-DNA conjugate. The attached marker DNA can be 20 amplified by PCR with the appropriate primers. As described in U.S. Patent 5,665,539, antigen is immobilized on the surface of microtiter plates and subsequently detected by immuno-PCR. Using this technique, an approximately 10^5 increase in sensitivity over an alkaline phosphatase 25 conjugated ELISA was obtained. Sensitivity advantages of immuno-PCR have subsequently been confirmed in assays for mouse anti-lipoprotein IgG (Ruzicka et al. Science 1993 260:698-699); a human proto-oncogene protein (Zhou et al. Nucleic Acid Res. 1993 21:6038-6039); and tumor necrosis 30 factor alpha (Sanna et al. Proc. Natl. Acad. Sci. 1995 92:272-275).

However, the original immuno-PCR protocol used a streptavidin-protein A chimera to detect the antigen-antibody complex. The variation in the affinity of

- 2 -

protein A against different classes of IgGs limits its direct application in the detection of a broad range of antigens. Certain improved protocols tried to solve this problem by introducing biotinylated secondary antibody or 5 free streptavidins.

Joerger et al. (Clin. Chem. 1995 41(9): 1371-1377) demonstrated that double-stranded DNA labels can be directly attached to antibodies, thus allowing conjugate reagents to be prepared before the assay.

10 Suzuki et al. (Jpn. J. Cancer Res. 1995 86:885-889) describe a method called double determinant immuno-polymerase chain reaction (double-determinant immuno-PCR) which utilizes two monoclonal antibodies, in which the antigens are sandwiched, and a specific DNA 15 molecule is used as a marker. In this method, the first monoclonal antibody to bind the circulating antigen is immobilized instead of the antigen itself. A biotinylated second monoclonal antibody is bound to the antigen and free streptavidin is used to attach a biotinylated DNA to the 20 second monoclonal antibody. The biotinylated DNA complexed with antigen-antibody-streptavidin is amplified by PCR. The products are then analyzed by Southern blot analysis.

While these immuno-PCR techniques have provided advantages over traditional methods of protein detection 25 such as an increase in sensitivity, there still exist several notable limitations to their use. One of the major limitations of immuno-PCR lies in the non-linear amplification ability of PCR reaction. There is no direct correlation between the amount of signal and the amount of 30 protein present. Thus, this technique is limited as a quantitative detection method.

U.S. Patent 5,922,553 discloses a method for quantifying levels of a selected protein via a technique referred to as immuno-aRNA. In this method, a first 35 antibody targeted to a selected protein is immobilized to a

- 3 -

solid support. The support is then contacted with the selected protein so that the selected protein is immobilized to the first antibody. The solid support is then contacted with a RNA promoter-driven cDNA sequence 5 covalently coupled to a second antibody targeted to the selected protein so that the second antibody binds to the bound selected protein. The amount of selected protein is determined by quantifying levels of the promoter driven cDNA sequence covalently coupled to the bound second 10 antibody via an amplified RNA technique. In a preferred embodiment, a T7 promoter driven cDNA sequence is covalently coupled to the second antibody.

It has now been found that single chain fragments as well as exocyclic peptide based complementarity determining 15 region (CDR) subunits can be used in this immuno-aRNA technique. Further, it has been found that PCR, as well as amplified RNA techniques, can be used to quantify the promoter driven cDNA sequence covalently coupled to the bound single chain fragment or CDR subunit. The use of 20 smaller antibody binding units and fragments coupled with the already existing large single chain or cyclic peptide libraries and the use of robotic assistance renders this method widely useful for both medicinal and research purposes. Furthermore, a single third detector species can 25 be coupled with double-stranded DNA and bound to either the single chain Fv or the CDRs, rendering detection uniform and simple. This is referred to herein as a universal detector.

Summary of the Invention

30 An object of the present invention is to provide a method for detecting molecules expressing a selected epitope in a sample. In this method, an epitope anchor specific for a selected epitope is immobilized to a selected surface. The epitope anchor may comprise a single 35 chain Fv fragment, a CDR, an antibody, or other ligand

- 4 -

peptide or chemical or pharmaceutical that interacts with a selected epitope. The surface is then contacted with a sample suspected of containing molecules which express the selected epitope so that the molecules bind to the
5 immobilized epitope anchor. An epitope detector comprising a single chain Fv for the selected epitope or a constrained epitope specific CDR attached to an oligonucleotide is then used to detect any bound molecules. In one embodiment, the single chain Fv or the CDR has been modified to allow for
10 attachment of oligonucleotides to a single site.

Alternatively, the method of the present invention can be performed with an epitope anchor. In this embodiment, the epitope detector is employed to define molecules bound directly to a surface.

15 Another object of the present invention is to provide systems for the detection of molecules expressing a selected epitope. These systems of the present invention comprise an epitope anchor specific for a selected epitope, a selected surface on which the epitope is or can be
20 immobilized, and an epitope detector comprising a single chain Fv for the selected epitope or a constrained epitope specific CDR attached to an oligonucleotide. In one embodiment, the single chain Fv or the constrained epitope specific CDR is modified to allow for attachment of the
25 oligonucleotides.

Yet another object of the present invention is to provide kits for the detection of molecules expressing a selected epitope which comprise an epitope anchor specific for a selected epitope and an epitope detector comprising a
30 single chain Fv for the selected epitope or a constrained epitope specific CDR attached to an oligonucleotide. In one embodiment, the single chain Fv or the constrained epitope specific CDR is modified to allow for attachment of the oligonucleotides.

Detailed Description of the Invention

The present invention relates to improved methods for quantifying levels of a selected molecule and systems and kits for performing these improved methods. In one 5 embodiment, the method comprises binding an epitope anchor specific for a selected epitope of the molecule to a selected surface. The epitope anchor may comprise a single chain Fv fragment, a CDR, an antibody, or other ligand peptide or chemical specific for a selected epitope. In a 10 preferred embodiment, the epitope anchor is bound to a designated spot on the surface. For example, the surface may comprise a chip and the epitope anchor is bound to a defined spot on the chip. In one embodiment, the epitope anchor is deposited onto a surface or plate with the aid of 15 a pipettor or similar device which permits application at a single site. The surface with the bound epitope anchor is then contacted with a sample suspected of containing molecules expressing the selected epitope so that the molecule binds to the epitope anchor. In another 20 embodiment, the molecule is attached to a surface directly, without the use of an epitope anchor.

Examples of samples which can be assayed via the methods of the present invention include, but are not limited to, individual cells and solutions including 25 biological fluids such as serum. An epitope detector which can bind to any bound molecule on the surface is then used to detect and quantify the amount of bound molecule. The epitope detector comprises a single chain Fv for the selected epitope or a constrained epitope specific CDR 30 which have been modified to allow for attachment of oligonucleotides at a single site.

Fv fragments for selected epitopes can be produced in cells or on microorganisms by use of recombinant DNA technology. For example, Skerra and Pluckthun (Science 35 1988 240:1038-1041) describe an expression system for

- 6 -

production of functional Fv fragments in *E. coli*.

A method for producing Fv fragments in eukaryotic host cells with a eukaryotic expression vector which has an operon having a DNA sequence which encodes the variable 5 domain only of an antibody light or heavy chain has also been described (J. Mol. Biol. 1988 203:825-828). Chains of the Fv fragment are secreted and correctly assembled by the host cell such that fully functional Fv fragments are produced in the culture supernatant. In addition, the DNA 10 coding sequence may be altered toward its 5' end so that the amino terminal end expresses a residue or residues with a surface suitable for covalent coupling of an oligonucleotide. In addition, the 3' terminal end may be varied so that cysteine residues are produced towards the 15 C-terminal end of each variable domain permitting the variable domains in the dimer to become linked together by disulphide bonding. This may also promote assembly of the Fv fragment. Alternatively, the Fv fragment may be stabilized by use of a vector having a first DNA sequence 20 encoding a first variable domain and a second DNA sequence encoding a second variable domain, the first and second sequences being linked by a third DNA sequence which encodes a joining peptide sequence. In this case, the joining peptide sequence is sufficiently long and flexible 25 to allow folding of the two polypeptides into a functional single chain Fv. Preferably, the host cell is a myeloma cell line which, prior to transformation, does not secrete whole antibody or light chains. Such cells lines are well known and widely available (Reichmann et al. J. Mol. Biol. 30 1988 203:825-828).

It is believed that random phage technology to any hapten or chemical compound can also be used to select Fvs. (Harrison et al. United States Biochemical Pharma Ltd. (Europe), Watford, United Kingdom)

35 The CDR technology is well known and has been

- 7 -

described in U.S. Patent 5,334,702, U.S. Patent 5,663,144, and U.S. Patent 5,919,764. In general, CDRs comprises a 6 to 15 mer peptide constrained to be cyclic and modified by aromatic residues. An important step in the design of 5 conformationally constrained peptides for use in the present invention is the delineation of the residues that are important for activity. This is generally accomplished by first synthesizing a set of analogs from the bioactive domain of the original antibody or receptor or ligand of 10 different lengths and establishing the minimal chain lengths for the complete and partial activities. Once the minimal chain length has been established, each side chain can be systematically varied to determine the importance of charge, steric bulk, hydrophobicity, aromaticity, and 15 chirality at each position. After evaluation of the properties of a large set of analogs, it is possible to identify the functional groups and conformation features involved in binding. Different conformationally constrained analogs can then be developed. Various means 20 for constraining peptides have been developed.

One means involves introducing a conformationally constrained amino acid. Hruby (Life Sci. 1982 31:189-199) describes the synthesis of a large number of amino acid and dipeptide derivatives with built-in conformational 25 constraints, as well as their incorporation into biologically active peptides. Prasad et al. (Biopolymers 1995 35:11-20) also describes a method of constraining the conformation of an amino acid unit by replacing the hydrogen atom at the α -carbon with a methyl group to 30 produce a dialkylamino acid. U.S. Patent 6,022,523 describes a method that restricts the conformational freedom of amino acids by introducing a double-bond at the C- α and C- β atoms.

Another means for constraining peptides involves 35 introduction of covalent cross-links. Constraining the

- 8 -

peptide backbone by introduction of covalent cross-links provides more dramatic effects than incorporating unusual amino acids. Macrocyclization is often accomplished by forming an amide bond between the peptide N- and C-termini, 5 between a side chain and the N or C terminus, or between two side chains. A head-to-tail cyclization of side protected peptides synthesized by Fmoc/t-butyl solid phase procedures on polystyrene resin derivatized with 4-hydroxymethyl-3-methoxyphenoxyacetic acid, the first 10 generation dialkoxy-benzyl linkage agent, has been described by Sheppard, R.C. (Int. J. Peptide Res. 1982 20:451-454). In addition, the analogous linkage agent, 4-(4-hydroxymethyl-3-methoxyphenoxy)-butyric acid (HAMA), was recently employed in fragment condensation and solid phase 15 synthesis of peptides with these highly acid sensitive linkers (In Peptides, E. Giralt and D. Andreu eds, ESCOM, Leiden, The Netherlands 1991, 131-133). The enkephalin analogs described by Schiller provide an example of side-chain to backbone covalent cyclization in which covalent 20 attachment of the e-amino group of the D-lys residue to the C terminal backbone carboxylate group of Leu produces a cyclic 16-membered ring analog with high potency and significant μ receptor selectivity (Schiller et al. Int. J. Pep. Prot. Res. 1985; 25:171-177). BOP-reagent and 25 carbodiimide/1-hydroxy-benzotriazole combinations have also been reported to be useful in the formation of cyclic peptides (Felix, A.M. Int. J. Pep. Prot. Res. 1988 31:231-238). Degrado et al. have also developed a biologically active cyclized peptide analog of the GP IIb/IIIa complex 30 using m-aminomethylbenzoic acid as the linker (U.S. Patent 6,022,523).

Disulphides can also be formed by oxidation via introduction of cysteine at certain positions. For example, Romani, S. (Int. J. Pep. Prot. Res. 1987 29:107-35 117) demonstrated that non-symmetrical disulphides can be

- 9 -

built with the help of the di-tertbutyl ester of azodicarboxylic acid. Ploux, O. (Int. J. Pep. Prot. Res. 1987 29:162-169) also describes a method for formation of non-symmetrical disulphides via thiol displacement of the 5 3S-3-nitro-2-pyridinesulfenyl group.

In a preferred embodiment, the oligonucleotide comprises a T7 promoter driven cDNA sequence so that it can be amplified using T7 RNA polymerase. In this embodiment, double stranded cDNA is synthesized for use as a template 10 for T7 RNA polymerase transcription. T7 RNA polymerase requires its promoter site to be double stranded.

In one embodiment, the site on the Fv or CDR to which the oligonucleotides are attached comprises a series of residues which allow the attachment of linkers consisting 15 of chemicals such as heterodimeric coupling reagents or other linkers. These residues provide a uniform binding site for the linker attachment. The linkers attach to this site and also links oligonucleotides to the Fv or CDR. Oligonucleotides may be unmodified or modified. For 20 example, the presence of the amplified oligonucleotide can be enhanced by incorporating a beacon or fluorescent labeled oligonucleotide into the mixture allowing for rapid semi quantitative assessment of the epitope expressing molecules (Tan et al., Chemistry Eur. J. 2000 6(7):1107- 25 1111; Leone et al., Nucleic Acids Res. 1998 26(9):2150- 2155).

Bound epitope detectors may be quantified by methods such as amplification by conventional PCR or aRNA 30 techniques. If the detection method used is immuno aRNA, double-stranded oligonucleotides are used in the epitope detector. In this embodiment, aRNA is transcribed on the solid support using a polymerase which recognizes a specific promoter such as T7 RNA polymerase, T3 RNA polymerase or SP6 RNA polymerase, unlabeled 35 ribonucleotides, and fluorescently labeled ribonucleotides.

- 10 -

A variety of means are available for detection of amplified products of the epitope detector. In one embodiment, the aRNA is detectably labeled such as with a radioactive label or a fluorescent label. Alternatively, 5 the aRNA can be converted to cDNA and detected via methods such as gel electrophoresis, high performance liquid chromatography, hybridization assays, immunohistochemical assays and/or specific binding protein assays.

Use of Fvs and CDR peptides as the epitope detector 10 renders this method useful in identifying larger polypeptides than can be identified by the immuno-aRNA technique of U.S. Patent 5,922,553, as well as in identifying motifs in supernatants, fluids, extracts of cells or bacteria or any other eukaryotic organism. 15 Accordingly, the method of the present invention has widespread applicability in both medicinal and research purposes. Further, the method of the present invention is more sensitive than currently available methods and provides quantitative results.

20 The ability of Fvs and CDR peptides to serve as epitope detectors of selected molecules in the method of the present invention was demonstrated for the p185 receptor. Using this method, the released p185 receptor was detected at a 10⁸-fold increase in sensitivity over the 25 ELISA and about a 1000-fold increase over the Western-ECL method. For these experiments, a single chain Fv (ScFv) construct of 7.16.4 (designated as 7.16.4 ScFv) was produced in accordance with the procedure outlined by Peterson & Greene (DNA and Cell Biology 1998 17(12):1031- 30 1040) wherein the Fv region of the heavy chain and light chain region was joined by a (gly4-Ser)5 linker. Since ScFv7.16.4 contained a poly-histidine tag, it was purified over Ni-NTA resin. After purification, the binding of 7.16.4ScFv was confirmed by FACS analysis on B104-1-1 35 cells, in both direct binding and competitive binding

- 11 -

against the monoclonal antibody 7.16.4.

AHNP, a constrained exocyclic peptide designed from the CDR3.H region of the anti-human p185 antibody 4D5 was also used. AHNP binds to p185 and mimics the growth-
5 inhibitory effects of 4D5 (Park et al. *Nature Biotechnology* 2000 18:194-198).

Both ScFv7.16.4 and AHNP were coupled to a double-stranded oligonucleotide (ds-oligo) to form epitope detectors. Both ds-oligo coupled 7.16.4ScFv and AHNP were
10 able to detect their antigens, rat p185neu from B104-1-1 cells and human p185her2/neu from T6-17 cells, respectively. Further, conjugation with the ds-oligo to form the epitope detector did not change the binding affinity of the CDR detection molecules with their antigens
15 as determined by plasmon resonance analysis. Since 7.16.4ScFv and mAb 7.16.4 have comparable binding affinity against the p185 receptor, they were used at comparable molar concentration in this assay. However, ANHP was used at a higher concentration since its affinity is lower
20 against p185Her2/neu than 4D5.

Coupling of a ds-oligo directly to the CDR or single chain Fv can be a time-consuming procedure, particularly if the purpose is to detect hundreds or thousands of antigens in a mass screening proteomic assay. In addition,
25 variation in the coupling efficiency can complicate the interpretation of the amplification results. Accordingly, in a preferred embodiment of the present invention, the Fv or CDR contains a general or universal epitope such as an hemagglutinin HA tag or polyhistidine tag. An example of a
30 general or universal epitope is the poly-His-tag in the 7.16.4ScFv initially designed for the purification of the protein. A single monoclonal antibody or single chain Fv coupled with ds-DNA is then used to bind to the general epitope to create a universal epitope detector. The
35 efficacy of a universal epitope detector in the method of

- 12 -

the present invention was demonstrated with the poly-His-tag in the 7.16.4ScFv. In these experiments, p185 receptors were captured by A11 coated on the plate, free 7.16.4ScFv was added, followed by extensive washing and 5 then incubating with ds-oligo conjugated anti-His antibody. After T7 polymerase amplification, specific bands from lysates of 10^{-6} dilution of the cells were detected. Accordingly, this sensitivity was even higher than that seen with the basic protocol without a universal epitope 10 detector.

The method of the present invention is also useful in the detection of post-translation modifications. PCR and aRNA techniques were originally developed to detect the activity of target genes at the DNA level. These methods 15 have been adopted exclusively in the application of genomics research, sometimes combined with hybridization. Regardless of sensitivity, these methods are not able to detect the post-translation modification at the protein level. Monitoring of such events, however, is very 20 critical since many modifications including, but not limited to, phosphorylation and glycosylation are related to the functional status of the protein. Thus, experiments were performed to demonstrate the ability of the method of the present invention to detect the phosphorylation of the 25 p185 receptor induced by EGF treatment. A signaling model was established in which, upon EGF stimulation, EGFR heterodimerizes with and trans-activates p185, resulting in the phosphorylation of tyrosine residues on the p185 receptor (Qian et al. Proc. Natl Acad. Sci. 1994 91:1500- 30 1504). The A431 cell line, which overexpresses EGFR as well as p185 erbB2, was used in these experiments. After EGF stimulation, the p185 receptor in the cell lysate was captured by 1E1, a monoclonal antibody developed against p185erbB2/neu. PY99, an IgG2b type of anti-phosphorylated 35 Tyr antibody, was used to detect phosphorylated receptors.

- 13 -

A second antibody, anti-IgG2b, coupled with ds-oligo, was used to probe the antigen-antibody sandwich complex. A431 cells stimulated with EGF produced a positive band, which was not observed in cells without EGF treatment. T6-17 5 cells, however, also showed a positive band, indicating constitutive phospho-tyrosine on the p185 receptor. These data indicate that this method is capable of detecting the functional status of a protein by analyzing its modification. Epitope detectors comprising an Fv or CDR 10 coupled to the ds-oligo can also be used to detect the functional status of the protein.

Thus, the present invention provides a sensitive detection method which eliminates concerns about the non-quantitative nature of immuno-PCR techniques and which 15 offers vast potential in the field of proteomics. By using a polymerase which recognizes a specific promoter such as T7 RNA polymerase, T3 RNA polymerase or SP6 RNA polymerase as well as the specific promoter in the amplification step, assays performed in accordance with this method possess 20 linear amplification and precise quantification which are relevant to biological and medical assays. The number of factors that affect the sensitivity of detection have also been reduced. The specific binding between antigens and their Fv or monovalent CDR is the only critical parameter 25 of this method.

The ability to provide universal epitope detectors provides the method of the present invention with multiple additional advantages. First, any cellular antigens can be detected without having been first coupled to a monoclonal 30 antibody with ds-oligo. Without the universal probe, the method would only be useful in looking at one or several particular antigens at a time. The universal probe, on the other hand, allows for the detection of any cellular or fluid residing antigen with available Fvs or CDRs. In 35 addition, with slight modification in the protocol,

different proteins can be detected simultaneously in a single electrophoresis lane when oligonucleotides of different sizes are attached to the Fv or CDR of the epitope detector. Thus, as demonstrated herein, the method 5 of the present invention provides a versatile technique that is applicable in the identification of protein antigens as well as post-translational modification of polypeptides and other structures such as sugars or lipids at the single cell level of detection.

10 It is believed that this method will also be useful in the analysis of protein interactions and the detection of small molecules. For example, ligand peptides can be used as epitope detectors on tissue samples to identify the expression of specific receptors, or vice versa. With 15 available Fvs, CDRs, or binding proteins, small molecules such as toxins or drug metabolites, can be detected in any solution including, but not limited to, water, foods, and body fluids.

20 The original immuno-PCR used pure antigens in the assay. Later iterations of Immuno-PCR examined mixed antigens (Hendrickson et al. Nucleic Acids Research 1995 23(3):522-529) but only showed sensitivity of two to three orders of magnitude higher than ELISA. In a real-world assay with the background comprising a huge variety of 25 non-specific antigens, sensitivity is always limited by the specificity of the assay. Epitopes bound by the Fvs or CDR fragments are expected to identify larger polypeptides and can be used to identify motifs in supernatants, fluids, extracts of cells or bacteria or any other eukaryotic 30 organism. Further, actual identity of the polypeptides, organic molecules or sugar structures can be determined by computer aided analysis of data bases using the binding of several epitopes by Fvs as a guide. For example, binding by Fv a, d, e, and f would identify a sugar molecule as 35 having side chains a, d, e, and f, and hence belonging to a

- 15 -

family of sugars having these same side chains. In this way the present invention allows definition and identification of many, if not all molecules in a cell at any one particular time. Moreover this approach can be
5 used to identify alternative transcriptional forms translated in an active cell or cellular supernatant. This procedure is easily amenable to 1) use with nonradioactive detection methods, 2) microtized liquid handling procedures, 3) low sample volume detection such as "protein
10 chip" analysis and 4) robotization.

The following nonlimiting examples are provided to further illustrate the present invention.

EXAMPLES

Example 1: Materials

15 Antibodies used include mAbs 7.16.4 and A11, each of which is reactive with a different epitope in the extracellular domain of p185neu. The polyclonal antiserum, α -Bacneu, directed against the intracellular domain of p185neu, was used for Western Blotting. 1E1 is an IgG1
20 monoclonal antibody generated against the ectodomain of human p185her2/neu. rhuMAb 4D5 (Herceptin) was obtained from Genentech. The anti-phosphotyrosine monoclonal antibody PY99 was obtained from Santa Cruz Biotechnology (Santa Cruz, CA). The cell line B104-1-1 was derived from
25 NIH3T3 cell by expressing rat oncogenic p185neu. The expression level of p185neu in B104-1-1 cells was determined using an 125 I-labeled anti-neu mAb binding assay. NR6, negative for both EGFR and p185neu, was a subclone from NIH3T3. T6-17 was derived from NIH3T3 by
30 over-expressing the human p185her2/neu receptor. These cell lines were all cultured in Dulbecco's Modified Eagle's medium (DMEM) containing 10% fetal bovine serum (FBS, Hyclone) at 37°C in a 5% CO₂ atmosphere.

Example 2: Immunoblotting procedures

- 16 -

Subconfluent cells in 10-cm dishes cells were washed twice with cold PBS and solubilized with PI/RIPA (1% Triton X-100, 1% deoxycholate, 0.1% SDS, 0.15 M NaCl, 0.01 M sodium phosphate-pH 7.4, 1% Aprotinin, 1 mM phenylmethylsulfonyl fluoride, 2 mM EDTA, 10 mM sodium pyrophosphate, 400 mM sodium orthovanadate, and 10 nM iodoacetamide buffer. Proteins were separated by proper concentration of SDS-PAGE and transferred to nitrocellulose membranes (Nitrobind, MSI). Membranes were incubated overnight with the blocking buffer (0.5% non-fat milk and 5% goat serum in PBS). For immunoblotting (Western blot) analysis, antibodies were diluted in PBS containing 0.1% non-fat milk and 1% goat serum. All polyclonal sera and secondary HRP-conjugated antibodies (Boehringer Mannheim) were used at a 1:5000 dilution. Bands were visualized using the ECL assay (Amersham).

Example 3: Expression and Purification of His-tagged 7.16.4

LB media (150 ml) containing 50 μ g/ml ampicillin was inoculated with a 15 ml overnight culture of *E. coli* DH5 α and maintained at 30°C until an optical density of 0.5 (600 nm) was obtained. Isopropyl- β -(D-thiogalactopyranoside) (IPTG) was added at a final concentration of 1 mM to induce His-tagged 7.16.4ScFv. After 3 hours, cells were harvested and lysed by freezing and thawing and resuspended in 10 ml of urea lysis buffer (10 mM Tris-Cl, pH 8.0, 0.1 M NaH₂PO₄, 1 M NaCl, 8 M urea) supplemented with 0.5 mM phenylmethylsulfonyl fluoride, 2 μ M pepstatin A, and 2 μ M leupeptin. The insoluble cellular debris was removed by centrifugation (12,000 x g for 15 minutes, followed by 12,000 x g for 30 minutes). The clarified supernatant was mixed with 2 ml of Ni-NTA agarose followed by gentle shaking on ice for 1 hour. The mixture was loaded into an empty column and unbound protein was washed with urea lysis buffer (pH 6.3) at 4°C. His-tagged protein was eluted with urea lysis buffer (pH 4.5), and eluate fractions were

- 17 -

examined by SDS-PAGE and FACS analysis as described in Example 4. Proteins in the peak fractions were pooled and dialyzed against TKC buffer (50 mM Tris-Cl, pH 8.0, 100 mM KCl, 10 mM CaCl₂, 1 mM EDTA, 0.1 mM PMSF).

5 **Example 4: Confirmation of 7.16.4ScFv binding by FACS Analysis**

Cell-surface antigens were detected by Fluorescence-activated cell sorting (FACS). B104-1-1 cells (about 5x10⁵) were incubated (30 minutes at 4°C) in 200 µl 10 of FACS buffer (PBS containing 0.5% bovine serum albumin and 0.02% sodium azide) containing the purified 7.16.4ScFv. Cells were then washed in FACS buffer and incubated (30 minutes, 4°C) with anti-His antibody (Invitrogen). After this second incubation, cells were washed again in FACS 15 buffer and further incubated with FITC-labeled IgG against mouse immunoglobulins (Sigma Chemical Co., St. Louis, MO). After washing with FACS buffer, the cell pellet was suspended in PBS buffer and processed for analysis by a FACS scan flow cytometer (Becton Dickinson). For each 20 sample, 10,000 viable cells were gated following size (forward scatter, FSC) and granularity (side scatter, SSC) parameters and analyzed with CellQuest Software (Becton Dickinson). For competitive binding, B104-1-1 cells were first incubated with the monoclonal antibody 7.16.4 in the 25 presence of different concentrations of 7.16.4ScFv. Cells were then washed in FACS buffer and further incubated with FITC-labeled IgG against mouse immunoglobulins (Sigma Chemical Co.) before analysis on the flow cytometer.

Example 5: **Attachment of ds-cDNA to Antibody or Fv or 30 CDR**

A cDNA oligonucleotide of the following sequence (GAGAGAGGATCCAAGTACTAATACGACTCACTATAGGGCCGAGAGCCGAGAAAGAAAGA CGTTTTTTTTT (SEQ ID NO:1)) was designed with an activatable amine at the 5' end to allow for covalent

- 18 -

coupling to primary amines and a T7 promotor site (TAATACGACTCACTATAGGG (SEQ ID NO:2)) used to direct the synthesis of RNA from the cDNA template through the enzymatic activity of T7 RNA polymerase. For attachment of 5 1 μ g of antibody to 30 μ g of ds cDNA, or 1 μ g CDR to 0.1 μ g ds cDNA or 1 μ g ScFv to 3 μ g ds cDNA, an equal volume of 0.1% glutaraldehyde was added in 10 μ l aliquots. The solution was mixed on a rotation device for 3 hours at room 10 temperature. Ethanolamine (1 M; 1/20 volume; pH 7.5) was then added. The solution was mixed for an additional 2 hours at room temperature. The protein-DNA complex was stored at 4°C.

Example 6: RNA amplification

RNA amplification was performed in 96-well plates 15 containing the first Ab-Antigen complex. The following reagents were added: 1X RNA amplification buffer (40 mM Tris-base, pH 7.5, 7 mM MgCl₂, 10 mM NaCl, 2 mM Spermidine; 5 mM DTT; 250 μ M ATP, UTP, GTP; 5 μ M CTP; 0.5 μ l RNAsin; 1000 U T7 RNA Polymerase and 3 μ l P³²-CTP. The solution was 20 then incubated for 4 hours at 37°C. The RNA product was removed from the wells and 3 μ l was added to 3 μ l of reaction stop solution (95% formamide, 10 mM EDTA, 0.1% bromophenol blue, 0.1% xylene cyanol) and electrophoresed on a 15% denaturing polyacrylamide gel. The gel was 25 apposed to a phosphoimager screen for 5-60 minutes and developed on a phosphoimager at 100 μ M resolution.

Example 7: Standard Sandwich ELISA as a Control Method

Ninety-six well microtiter plates (Nunc-Immuno Plate, MaxiSorpTM) were coated with the 1E1 (a monoclonal antibody 30 directed against the extracellular domain of human p185) by incubating plates overnight at 4°C with 100 μ l of coating buffer (antibody concentration: 5 μ g/ml). Plates were then washed three times with PBS containing 0.2% TWEEN 20 (PBS-T; 200 μ l/well), blocked with PBS containing 0.5% FBS

- 19 -

and 0.2% TWEEN 20 (200 μ l/well) for 1 hour at room temperature, and washed again three times with PBS-T (200 μ l/well). In parallel, 100 μ l of a serial dilution of T6-17 cell lysates were added to the plate and incubated 5 for 2 hours at room temperature. After this incubation step, plates were washed with PBS-T (six times, 200 μ l/well) and incubated with humanized anti-p185Her2 antibody 4D5 (150 ng/ml, 50 μ l/well) for 2 hours at room temperature. Subsequently, plates were washed six times 10 and incubated with 50 μ l of anti-human IgG-HRP (Zymed; final dilution: 1:10,000) for another 2 hours at room temperature. Enzymatic reactions were carried out at room temperature by adding TMB (2.5 mM each in 0.1 M phosphate-citrate buffer, pH 5.0) (100 μ l of each 15 reagent/well). Reactions were stopped after 15-60 minutes by the addition of 50 μ l of 1 M H₂SO₄. Color development was measured at 450 nm using the ELISA reader.

- 20 -

What is Claimed is:

1. A method for detecting molecules expressing a selected epitope in a sample comprising:
 - (a) immobilizing a molecule expressing a selected epitope in a sample to a selected surface;
 - (b) contacting the surface with an epitope detector so that the epitope detector binds to immobilized molecules on the surface; and
 - (c) detecting any epitope detector bound to the surface, wherein bound epitope detector is indicative of molecules expressing the selected epitope in the sample.
2. The method of claim 1 wherein the molecule expressing a selected epitope is immobilized to the selected surface via binding to an epitope anchor on the surface which is specific for the selected epitope.
3. The method of claim 1 wherein the epitope detector comprises a universal epitope detector which detects a general epitope.
- 20 4. The method of claim 1 wherein the detected molecule is post-translationally modified.
5. A system for the detection of molecules expressing a selected epitope comprising:
 - (a) a selected surface on which a molecule expressing a selected epitope is or can be immobilized; and
 - (b) an epitope detector comprising a single chain Fv for the selected epitope or a constrained epitope specific CDR either of which have been modified to allow for attachment of oligonucleotides.
- 30 6. The system of claim 5 further comprising an epitope anchor for immobilizing the molecule to the

- 21 -

selected surface, said epitope anchor being specific for the selected epitope.

7. The system of claim 5 wherein the epitope detector comprises a universal epitope detector which 5 detects a general epitope.

8. A kit for the detection of molecules expressing a selected epitope comprising an epitope detector comprising a single chain Fv for the selected epitope or a constrained epitope specific CDR.

10. 9. The kit of claim 8 further comprising an epitope anchor specific for the selected epitope.

10. The kit of claim 8 wherein the single chain Fv or the constrained epitope specific CDR have been modified 15 for attachment of oligonucleotides.

11. The kit of claim 8 wherein the epitope detector comprises a universal epitope detector which detects a general epitope.
